Untyped Lambda Calculus

We can boil down computation to a tiny calculus

Untyped Lambda Calculus - Recapitulation

We can boil down computation to a tiny calculus

All we need is:

- Function Definition / Abstraction ($\lambda x.e$)
- Function Application ($e\ e$)
- Parameters / Variables (x)

Untyped Lambda Calculus - Recapitulation

We can boil down computation to a tiny calculus

All we need is:

- Function Definition / Abstraction ($\lambda x.e$)
- Function Application ($e\ e$)
- Parameters / Variables (x)

Then we get:

- Booleans
- Numerals
- Data Structures
- Control Flow
- …

Untyped Lambda Calculus - Recapitulation

We can boil down computation to a tiny calculus

All we need is:

- Function Definition / Abstraction ($\lambda x.e$)
- Function Application ($e\ e$)
- Parameters / Variables (x)

Then we get:

- Booleans
- Numerals
- Data Structures
- Control Flow
- …

Turing Completeness

- If it can be computed, it can be computed in Lambda Calculus!

Example - $(\lambda p.\lambda q.p) \ a \ b$

$$(\lambda p. \quad \lambda q.p \quad) \quad a \quad b$$

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)\ a\ b$

$$(\lambda p. \quad \lambda q.p \quad) \quad a \quad b \qquad \text{Substitute } p \mapsto a$$

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)\ a\ b$

$(\lambda p. \quad \lambda q.p \quad) \quad a \quad b \quad$ Substitute $p \mapsto a$

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)$ a b

$(\lambda p.$	$\lambda q.p$	)	a	b	Substitute $p \mapsto a$
(	$\lambda q.a$	)		b	

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)$ a b

$(\lambda p.$	$\lambda q.p$	$)$	a	b	Substitute $p \mapsto a$
$($	$\lambda q.a$	$)$		b	Substitute $q \mapsto b$

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)\ a\ b$

$(\lambda p.$	$\lambda q.p$	$)$	a	b	Substitute $p \mapsto a$
$($	$\lambda q.a$	$)$		b	Substitute $q \mapsto b$

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function $(\lambda q.p)$

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Example - $(\lambda p.\lambda q.p)\ a\ b$

$(\lambda p.$	$\lambda q.p$	$)$	a	b	Substitute $p \mapsto a$
$($	$\lambda q.a$	$)$		b	Substitute $q \mapsto b$
$($	a	$)$			

Meaning

$\lambda p.\lambda q.p$ Is a function that returns a function ($\lambda q.p$)

a, b Some variables (defined somewhere else)

p Is a variable that is bound to the parameter with the same name

Build an Interpreter

Let's build an interpreter

- Deepen our intuition
- Later move on to the *Simply Typed Lambda Calculus*
  - Why do we need types?
  - How does a type checker work?
  - How does it restrict the programs we might write?
- We'll do *Math Driven Development*
  - Look at the concepts in math first, then translate them to Haskell

Structure

$$
\begin{array}{rl}
e ::= & \text{Expressions:} \\
x & \text{Variable} \\
\lambda x.e & \text{Abstraction} \\
e\ e & \text{Application}
\end{array}
$$

$\lambda x.e$ Function Definition

$e\ e$ Function Application (Function Call)

Abstract Syntax Tree

$(\lambda x.x)\ y$
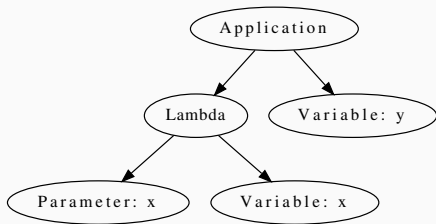

Meaning

- Identity function $(\lambda x.x)$ is applied to a variable (y)

```
module UntypedSyntax where

type Name = String

data Expr                    -- e ::=          Expressions:
  = Var Name                 --      x         Variable
  | Lambda Name              --      λx.e      Abstraction
          Expr
  | App Expr                 --      e e       Application
      Expr
  deriving (Eq, Show)
```

```haskell
module UntypedSyntaxExamples where

import UntypedSyntax

-- id ≡ λx.x
id :: Expr
id = Lambda "x" $ Var "x"
```

```haskell
module UntypedSyntaxExamples where

import UntypedSyntax

-- id ≡ λx.x
id :: Expr
id = Lambda "x" $ Var "x"
```

```haskell
-- true ≡ λp.λq.p
true :: Expr
true = Lambda "p" (Lambda "q" (Var "p"))

-- false ≡ λp.λq.q
false :: Expr
false = Lambda "p" (Lambda "q" (Var "q"))
```

```
-- and ≡ λp.λq.p q p
and :: Expr
and = Lambda "p" $ Lambda "q" $ App (App (Var "p") (Var "q")) (Var "p")
```

Natural Deduction

Notation

$$\frac{}{\textit{Axiom}} \tag{A1}$$

$$\frac{\textit{Antecedent}}{\textit{Conclusion}} \tag{A2}$$

Meaning

Axiom Rule without Precondition

Antecedent Precondition - if it's fulfilled this rule applies.

Conclusion What follows from this rule.

A1, A2 Names for the rules

Proof: 2 is a Natural Number

$$\frac{}{0 : \mathtt{Nat}} \qquad \text{(A1)}$$

$$\frac{n : \mathtt{Nat}}{\mathtt{succ}(n) : \mathtt{Nat}} \qquad \text{(A2)}$$

Meaning

A1 0 is a natural number (by definition)

A2 The successor of a natural number is a natural number

Proof: 2 is a Natural Number

$$\overline{0 : \mathtt{Nat}} \quad \text{(A1)}$$

$$\frac{n : \mathtt{Nat}}{\mathrm{succ}(n) : \mathtt{Nat}} \quad \text{(A2)} \qquad \frac{\dfrac{\overline{0 : Nat} \quad \text{(A1)}}{succ(0) : Nat} \quad \text{(A2)}}{succ(succ(0)) : Nat} \quad \text{(A2)}$$

Meaning

A1 0 is a natural number (by definition)

A2 The successor of a natural number is a natural number

$\rightarrow$ Thus the successor of the successor of 0 (2) must be a natural number

Evaluation Rules

Evaluation Rules - Call by Value - E-App1

$$\frac{e_1 \rightarrow e_1'}{e_1 e_2 \rightarrow e_1' e_2} \qquad \text{E-App1}$$

Meaning

- Under the condition that e_1 can be reduced further, do it.

$$\frac{e_1 \to e_1'}{e_1 e_2 \to e_1' e_2}$$

Example

$$\overbrace{((\lambda x.x)\ (\lambda y.y))}^{e_1}\ e_2$$

$$\frac{e_1 \rightarrow e_1'}{e_1 e_2 \rightarrow e_1' e_2}$$

Example

$$\overbrace{((\lambda x.x)\ (\lambda y.y))}^{e_1}\ e_2$$

$$\frac{e_1 \rightarrow e_1'}{e_1\, e_2 \rightarrow e_1'\, e_2}$$

Example

$$\overbrace{((\lambda x.x)\ (\lambda y.y))}^{e_1}\ e_2$$
$$\rightarrow (\lambda y.y)\ z$$

Evaluation Rules - Call by Value - E-App2

$$\frac{e_2 \rightarrow e'_2}{v_1\, e_2 \rightarrow v_1\, e'_2} \qquad \text{E-App2}$$

Meaning

- Under the condition that e_2 can be reduced further and v_1 is a value, do it.
- "Bare" Untyped Lambda Calculus:
    - Only Lambdas (functions) are values.
    - But you can add Ints, Booleans, etc. ("Enriched Untyped Lambda Calculus")

Evaluation Rules - E-App2 - Example

$$\frac{e_2 \rightarrow e_2'}{v_1\, e_2 \rightarrow v_1\, e_2'} \qquad \text{E-App2}$$

Example

$$\overbrace{(\lambda x.x)}^{v_1}\ \overbrace{((\lambda y.y)\ 42)}^{e_2}$$

$$\frac{e_2 \to e_2'}{v_1 e_2 \to v_1 e_2'} \qquad \text{E-App2}$$

Example

$$\overbrace{(\lambda x.x)}^{v_1} \ \overbrace{((\lambda y.y) \ 42)}^{e_2}$$

$$\frac{e_2 \rightarrow e_2'}{v_1\,e_2 \rightarrow v_1\,e_2'} \qquad \text{E-App2}$$

Example

$$\overbrace{(\lambda x.x)}^{v_1}\ \overbrace{((\lambda y.y)\ 42)}^{e_2}$$
$$\rightarrow (\lambda x.x)\ 42$$

$$\frac{e_2 \rightarrow e_2'}{v_1 e_2 \rightarrow v_1 e_2'} \qquad \text{E-App2}$$

Example

$$\overbrace{(\lambda x.x)}^{v_1} \overbrace{((\lambda y.y)\ 42)}^{e_2}$$

$$\rightarrow (\lambda x.x)\ 42$$

Note

- We evaluate the parameter before applying the function: Eager Evaluation!

$$(\lambda x.e)v \rightarrow [x/v]e \qquad \text{E-AppLam}$$

Meaning

- If a lambda (function) is applied to a value, substitute that value for it's parameter.
- "substitute" : replace it for every occurence in the lambda's body

Evaluation Rules - E-AppLam -Example

$$(\lambda x.e)v \rightarrow [x/v]e \qquad \text{E-AppLam}$$

Example

$$(\lambda x.\lambda y.x) \; z$$

$$(\lambda x.e)v \rightarrow [x/v]e \qquad \text{E-AppLam}$$

Example

$$(\lambda x.\lambda y.x)\ z$$

$$(\lambda x.e)v \rightarrow [x/v]e \qquad\qquad \text{E-AppLam}$$

Example

$$(\lambda x.\lambda y.x)\ z$$
$$\rightarrow \lambda y.z$$

Interpreter - Evaluation

```
module UntypedEval where

import UntypedSyntax

eval :: Expr -> Expr
-- No rule for variables
eval variable@(Var _) = variable
-- No rule for lambdas
eval lambda@(Lambda _ _) = lambda
```

```
eval (App e1 e2)
--
--   e₁→e₁'        (E − App1)
--  ─────────
--   e₁ e₂→e₁' e₂
--
 =
  let e1' = eval e1
--
--   e₂→e₂'        (E − App2)
--  ─────────
--   v₁ e₂→v₁ e₂'
--
   in let e2' = eval e2
       in case e1'
                  of
--
-- (λx.e)v → [x/v]e   (E − AppLam)
--
              (Lambda x e1'_body) -> eval $ substitute x e2' e1'_body
              e1' -> App e1' e2'
```

Interpreter - Substitution

```haskell
substitute :: Name -> Expr -> Expr -> Expr
--
-- If the Name matches: Substitute this Var by it's substitution
-- Otherwise: Leave it as is
--
substitute name substitution var@(Var varName)
  | name  == varName = substitution
  | otherwise = var
--
-- Recursively substitute in both parts of Applications
--
substitute name substitution (App term1 term2) =
  App (substitute name substitution term1) (substitute name substitution term2)
```

```
--
-- Only substitute in Lambda's body, if the parameter doesn't
-- redefine the Name in it's scope
--
substitute name substitution (Lambda varName term) =
  if name == varName
    then Lambda varName term
    else Lambda varName (substitute name substitution term)
```

Tests

```haskell
module UntypedEvalExamplesSpec where

import NaiveUntypedEval
import Prelude hiding (and)
import Test.Hspec
import UntypedSyntax
import UntypedSyntaxExamples

main :: IO ()
main = hspec spec

spec :: Spec
spec =
  describe "eval" $
    it "should evaluate these terms"  $ do
--
-- a → a
--
      eval (Var "a") `shouldBe` Var "a"
```

Tests

```
--
-- true ≡ λp.λq.p
--
-- true a b → a
--
    eval (App (App true (Var "a")) (Var "b")) `shouldBe` Var "a"
```

Tests

```
--
-- true ≡ λp.λq.p
--
-- true a b → a
--
     eval (App (App true (Var "a")) (Var "b")) `shouldBe` Var "a"
```

```
--
-- false ≡ λp.λq.q
--
-- and ≡ λp.λq.p q p
--
-- and true false → false
--
     eval (App (App and true) false) `shouldBe`
       Lambda "p" (Lambda "q" (Var "q"))
```

Simply Typed Lambda Calculus

Structure

$$e ::= \qquad\qquad\qquad \text{Expressions:}$$

$$x \qquad\qquad\qquad \text{Variable}$$

$$\lambda x : \tau.e \qquad\qquad\qquad \text{Abstraction}$$

$$e\ e \qquad\qquad\qquad \text{Application}$$

τ Type of the parameter x

- Bool, Int, …

What's a Type?

A Type is a set of values that an expression may return:

> **Bool** True, False
>
> **Int** $[-2^{29}..2^{29} - 1]$ (in Haskell, 'Data.Int')

Simple types don't have parameters, no polymorphism:

> `Bool, Int` have no parameters $\rightarrow$ simple types
>
> `Maybe a` takes a type parameter (a) $\rightarrow$ not a simple type
>
> `a -> a` is polymorphic $\rightarrow$ not a simple type

Type Safety = Progress + Preservation

Progress : If an expression is well typed then either it is a value, or it can be further evaluated by an available evaluation rule.

- A well typed (typable) program never gets "stuck".

Type Safety = Progress + Preservation

Progress : **If an expression is well typed then either it is a value, or it can be further evaluated by an available evaluation rule.**

- A well typed (typable) program never gets "stuck".

Preservation : **If an expression e has type τ, and is evaluated to e', then e' has type τ.**

- $e \equiv (\lambda x : Int.x)1$ and $e' \equiv 1$ have both the same type: Int

Not all meaningful Programs can be type checked

```
id :: a -> a
id a = a
```

- It strongly depends on the type system if this is allowed or not.
- In Simply Typed Lambda Calculus it's not!
    - No polymorphic types …

Evalution rules stay the same!

- Type checking is done upfront

Typing Rules - Variables

$$\frac{x : \sigma \in \Gamma}{\Gamma \vdash x : \sigma} \qquad \text{T-Var}$$

Meaning

Γ The Typing Environment, a list of (*Variable* : *Type*) pairs (associations)

Condition If (x, σ) is in the Typing Environment

Conclusion x has type σ

Typing Rules - Variables - Example

$$\frac{x : \sigma \in \Gamma}{\Gamma \vdash x : \sigma} \qquad \text{T-Var}$$

Example

$$\underbrace{\lambda x : \mathit{Int}}_{\Gamma' = \Gamma, x : \mathit{Int}} . \underbrace{\lambda y : \mathit{Bool}}_{\Gamma'' = \Gamma', y : \mathit{Bool}} . \underbrace{x}_{\Gamma'' \vdash x : \mathit{Int}}$$

$\lambda x : \mathit{Int}$ Add $x : \mathit{Int}$ to the Typing Environment (Γ)

x We know from the Typing Environment (Γ'') that x has type Int

Typing Rules - Constants

$$\Gamma \vdash n : \mathsf{Int} \qquad\qquad \text{T-Int}$$

$$\Gamma \vdash \mathsf{True} : \mathsf{Bool} \qquad\qquad \text{T-True}$$

$$\Gamma \vdash \mathsf{False} : \mathsf{Bool} \qquad\qquad \text{T-False}$$

Meaning

`True, False` literals / constants are of type `Bool`

n number literals / constants are of `Int`

Why do we need Γ here?

- We handle Type Constructors like variables
- Think: $\Gamma \equiv \emptyset, True : Bool, False : Bool, 0 : Int, 1 : Int, \ldots$

Typing Rules - Constants - Example

$$\Gamma \vdash n : \text{Int} \qquad \text{T-Int}$$

$$\Gamma \vdash \text{True} : \text{Bool} \qquad \text{T-True}$$

Example

$\Gamma \equiv \emptyset, \textit{True} : \textit{Bool}, \textit{False} : \textit{Bool}, 0 : \textit{Int}, 1 : \textit{Int}, \ldots$

True

1

$$\Gamma \vdash n : \text{Int} \qquad\qquad \text{T-Int}$$

$$\Gamma \vdash \text{True} : \text{Bool} \qquad\qquad \text{T-True}$$

Example

$\Gamma \equiv \emptyset, \textit{True} : \textit{Bool}, \textit{False} : \textit{Bool}, 0 : \textit{Int}, 1 : \textit{Int}, \ldots$

True

1

$$\Gamma \vdash n : \text{Int} \qquad\qquad \text{T-Int}$$

$$\Gamma \vdash \text{True} : \text{Bool} \qquad\qquad \text{T-True}$$

Example

$\Gamma \equiv \emptyset, \mathit{True} : \mathit{Bool}, \mathit{False} : \mathit{Bool}, 0 : \mathit{Int}, 1 : \mathit{Int}, \dots$

True

1

Typing Rules - Lambdas

$$\frac{\Gamma, x : \tau_1 \vdash e : \tau_2}{\Gamma \vdash \lambda x : \tau_1.e : \tau_1 \to \tau_2} \qquad \text{T-Lam}$$

Meaning

Condition With $x : \tau_1$ in the Typing Environment, e has type τ_2

Conclusion $\lambda x : \tau_1.e$ has type $\tau_1 \to \tau_2$

Because e has type τ_2 if x has type τ_1

Typing Rules - Lambdas - Example

$$\frac{\Gamma, x : \tau_1 \vdash e : \tau_2}{\Gamma \vdash \lambda x : \tau_1.e : \tau_1 \to \tau_2} \qquad \text{T-Lam}$$

Example

$$\lambda x : \overbrace{Int}^{\tau_1} . \overbrace{x}^{e} \qquad \qquad :?$$

Typing Rules - Lambdas - Example

$$\frac{\Gamma, x : \tau_1 \vdash e : \tau_2}{\Gamma \vdash \lambda x : \tau_1.e : \tau_1 \rightarrow \tau_2} \qquad \text{T-Lam}$$

Example

$$\lambda x : \overbrace{Int}^{\tau_1} . \overbrace{x}^{e} \qquad\qquad :?$$

$$\frac{\Gamma, x : Int \vdash e : Int}{\Gamma \vdash \lambda x : Int.e : Int \rightarrow Int}$$

$$\frac{\Gamma, x : \tau_1 \vdash e : \tau_2}{\Gamma \vdash \lambda x : \tau_1.e : \tau_1 \to \tau_2} \qquad \text{T-Lam}$$

Example

$$\lambda x : \overbrace{Int}^{\tau_1} . \overbrace{x}^{e} \qquad\qquad : \overbrace{Int}^{\tau_1} \to \overbrace{Int}^{\tau_2}$$

$$\frac{\Gamma, x : Int \vdash e : Int}{\Gamma \vdash \lambda x : Int.e : Int \to Int}$$

Typing Rules - Applications

$$\frac{\Gamma \vdash e_1 : \tau_1 \rightarrow \tau_2 \quad \Gamma \vdash e_2 : \tau_1}{\Gamma \vdash e_1 e_2 : \tau_2} \qquad \text{T-App}$$

Meaning

Condition If e_1 is a function of type $\tau_1 \rightarrow \tau_2$ and e_2 has type τ_2

Conclusion Then the type of $e_1 e_2$ (function application) is τ_2

Typing Rules - Applications

$$\frac{\Gamma \vdash e_1 : \tau_1 \rightarrow \tau_2 \quad \Gamma \vdash e_2 : \tau_1}{\Gamma \vdash e_1 e_2 : \tau_2} \qquad \text{T-App}$$

Meaning

Condition If e_1 is a function of type $\tau_1 \rightarrow \tau_2$ and e_2 has type τ_2

Conclusion Then the type of $e_1 e_2$ (function application) is τ_2

```
id' :: Int -> Int
id' i = i

1 :: Int
(id' 1) :: Int
```

Typing Rules - Applications - Example

$$\frac{\Gamma \vdash e_1 : \tau_1 \rightarrow \tau_2 \quad \Gamma \vdash e_2 : \tau_1}{\Gamma \vdash e_1 e_2 : \tau_2} \qquad \text{T-App}$$

Example

$$\overbrace{(\lambda x : \mathit{Int}. \mathit{True})}^{e_1} \overbrace{42}^{e_2} \qquad\qquad :?$$

Typing Rules - Applications - Example

$$\frac{\Gamma \vdash e_1 : \tau_1 \to \tau_2 \quad \Gamma \vdash e_2 : \tau_1}{\Gamma \vdash e_1 e_2 : \tau_2} \qquad \text{T-App}$$

Example

$$\overbrace{(\lambda x : \mathit{Int}.\mathit{True})}^{e_1} \overbrace{42}^{e_2} \qquad \qquad :?$$

$$\frac{\Gamma \vdash \overbrace{(\lambda x : \mathit{Int}.\mathit{True})}^{e_1} : \overbrace{\mathit{Int} \to \mathit{Bool}}^{\tau_1 \to \tau_2} \quad \Gamma \vdash \overbrace{42}^{e_2} : \overbrace{\mathit{Int}}^{\tau_1}}{\Gamma \vdash \underbrace{(\lambda x : \mathit{Int}.\mathit{True})}_{e_1} \underbrace{42}_{e_2} : \underbrace{\mathit{Bool}}_{\tau_2}}$$

Typing Rules - Applications - Example

$$\frac{\Gamma \vdash e_1 : \tau_1 \to \tau_2 \quad \Gamma \vdash e_2 : \tau_1}{\Gamma \vdash e_1 e_2 : \tau_2} \qquad \text{T-App}$$

Example

$$\overbrace{(\lambda x : \mathit{Int}.\mathit{True})}^{e_1} \overbrace{42}^{e_2} \qquad\qquad\qquad : \overbrace{\mathit{Bool}}^{\tau_2}$$

$$\frac{\Gamma \vdash \overbrace{(\lambda x : \mathit{Int}.\mathit{True})}^{e_1} : \overbrace{\mathit{Int} \to \mathit{Bool}}^{\tau_1 \to \tau_2} \quad \Gamma \vdash \overbrace{42}^{e_2} : \overbrace{\mathit{Int}}^{\tau_1}}{\Gamma \vdash \underbrace{(\lambda x : \mathit{Int}.\mathit{True})}_{e_1} \underbrace{42}_{e_2} : \underbrace{\mathit{Bool}}_{\tau_2}}$$

```
module TypedSyntax where

import qualified Data.Map.Strict as Map

type Name = String
type Error = String

data Expr                    -- e ::=                    Expressions :
  = IntValue Int             --      [−2^29..2^29 − 1]       Integer Literal
  | BoolValue Bool           --      True | False            Boolean Literal
  | Var Name                 --      x                       Variable
  | App Expr                 --      e e                     Application
        Expr
  | Lambda Name              --      λx: τ.e                 Abstraction
          Type
          Expr
  deriving (Eq, Show)
```

```haskell
type Environment = Map.Map Name Type

data Type                    -- τ ::=              Types :
  = TInt                     --      Int           Integer
  | TBool                    --      Bool          Boolean
  | TArr Type                --      τ₁ → τ₂       Abstraction / Function
         Type
  deriving (Eq, Show)
```

Type Checker - Literals

```haskell
module TypedCheck where

import Data.Either.Extra
import qualified Data.Map.Strict as Map

import TypedSyntax

check :: Environment -> Expr -> Either Error Type
--
-- Γ ⊢ n : Int   (T-Int)
--
check _ (IntValue _) = Right TInt
--
-- Γ ⊢ True : Bool   (T-True)
--
check _ (BoolValue True) = Right TBool
--
-- Γ ⊢ False : Bool   (T-False)
--
check _ (BoolValue False) = Right TBool
```

```
--
--   Γ,x:τ₁⊢e:τ₂      (T-Lam)
--  ─────────────────
--   Γ⊢λx:τ₁.e:τ₁→τ₂
--
check env (Lambda x t1 e) = do
  t2 <- check (Map.insert x t1 env) e
  return $ TArr t1 t2
```

Type Checker - Application

```
--
--  Γ⊢e₁:τ₁→τ₂   Γ⊢e₂:τ₁    (T-App)
         Γ⊢e₁e₂:τ₂
--
check env (App e1 e2) = do
  te1 <- check env e1
  case te1 of
    (TArr t1 t2) -> do
      te2 <- check env e2
      if t1 == te2
        then Right t2
        else Left $ "Expected " ++ (show t1) ++ " but got : " ++ (show te2)
    _ -> Left $ "Expected TArr but got : " ++ (show te1)
```

```
--
-- x:σ∈Γ    (T-Var)
-- ───────
-- Γ⊢x:σ
--
check env (Var x) = find env x

find :: Environment -> Name -> Either Name Type
find env name = maybeToEither "Var not found!" (Map.lookup name env)
```

Tests

```
module TypedCheckExamplesSpec where

import Test.Hspec
import TypedCheck
import TypedSyntax

import qualified Data.Map.Strict as Map

main :: IO ()
main = hspec spec
```

Tests

```haskell
spec :: Spec
spec = do
  describe "check" $
    it "should type check these terms" $
--
-- (λx : Int.x) 42 :: Int
--
      do
       check Map.empty (App (Lambda "x" TInt (Var "x")) (IntValue 5))
         `shouldBe` Right TInt
```

Tests

```
spec :: Spec
spec = do
  describe "check" $
    it "should type check these terms" $
--
-- (λx : Int.x) 42 :: Int
--
      do
       check Map.empty (App (Lambda "x" TInt (Var "x")) (IntValue 5))
         `shouldBe` Right TInt
```

```
--
-- Does not type check: (λx : Bool.x) 42
--
      check Map.empty (App (Lambda "x" TBool (Var "x")) (IntValue 5))
        `shouldBe` Left "Expected TBool but got : TInt"
```

Tests

```
--
-- Does not type check: 42 False
--
    check Map.empty (App (IntValue 42) (BoolValue False)) `shouldBe`
      Left "Expected TArr but got : TInt"
```
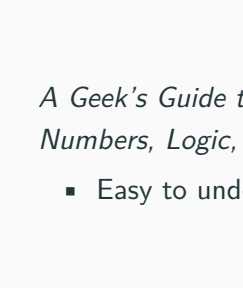

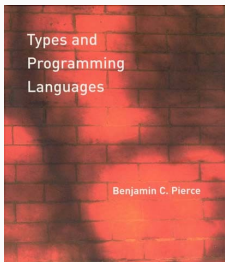

End

Thanks

- Hope you enjoyed this talk and learned something new.
- Hope it wasn't too much math and dusty formulas … :)

A Geek's Guide to the Beauty of Numbers, Logic, and Computation

- Easy to understand

Types and Programming Languages

Types and
Programming
Languages

Benjamin C. Pierce

- Types systems explained by building interpreters / checkers and proving properties
- Very "mathematical", but very complete and self-contained

Building a modern functional compiler from first principles.

- Starts with the Lambda Calculus and goes all the way down to a full Haskell compiler
- Available for free - Not finished, yet
